Trees

2/20/2012

(c) 2001-4, University of Washington

22.1

Tree Definitions

- A **tree** is a collection of **nodes** connected by **edges**
- A **node** contains
 - Data (e.g. an Object)
 - References (edges) to two or more **subtrees** or **children**
- Trees are hierarchical
 - A node is said to be the **parent** of its **children** (subtrees)
 - There is a single unique **root** node that has no parent
 - Nodes with no children are called **leaf nodes**
 - A tree with no nodes is said to be **empty**

2/20/2012

(c) 2001-4, University of Washington

22.2

Tree Terminology

Trees usually drawn upside-down, from root to leaves

2/20/2012

(c) 2001-4, University of Washington

22.3

Subtrees

- A **subtree** in a tree is any node in the tree together with all of its descendants (its children, and their children, recursively)

2/20/2012

(c) 2001-4, University of Washington

22.4

Level and Height

Definition: The root has **level 1**

Children have level 1 greater than their parent

Definition: The **height** is the highest level of any node in a tree.

2/20/2012

(c) 2001-4, University of Washington

22.5

Binary Trees

- A **binary tree** is a tree each of whose nodes has no more than two children
 - The two children are called the **left child** and **right child**
 - The subtrees belonging to those children are called the **left subtree** and the **right subtree**

2/20/2012

(c) 2001-4, University of Washington

22.6

Binary Tree Nodes

- A node for a binary tree holds the item and references to its subtrees

```
class BTreeNode<E> {  
    E item;           // data item in this node  
    BTreeNode left;   // left subtree, or null if none  
    BTreeNode right;  // right subtree, or null if none  
  
    BTreeNode(Object item, BTreeNode left, BTreeNode right) { ... }  
}
```

- Where could we put this class definition?
- What would BinaryTree class instance variable(s)/constructor look like?
- What operations on a BinaryTree might there be (add, remove, query)?

2/20/2012

(c) 2001-4, University of Washington

22-7

Tree Algorithms

- The definition of a tree is naturally recursive:
 - A tree is either null (empty),
or data + left (sub-)tree + right (sub-)tree
 - Base case(s)?
 - Recursive case(s)?
- Given a recursively defined data structure, recursion is often a very natural technique for algorithms on that data structure
 - Don't fight it!

2/20/2012

(c) 2001-4, University of Washington

22-8

A Typical Tree Algorithm: size()

```
// within BinTree  
/** Return the number of items in this tree */  
public int size() {  
    return subtreeSize(root);  
}  
  
// Return the number of nodes in the (sub-)tree with root n  
private int subtreeSize(BTreeNode<E> n) {  
    if (n == null)  
        return _____ ;  
    else  
        return _____ ;  
}
```

What is runtime cost of this algorithm?

22-9

Exercises

Do try these at home!

1. Print all the contents of the binary tree (BT)
2. Find the sum of all the values in a BT of integers
3. Find the smallest value in a BT of integers
4. (A little harder) Find the average of all the values in a BT (one approach: think in terms of a "kickoff" method)

2/20/2012

(c) 2001-4, University of Washington

22-10

Tree Traversal

- Functions like subtreeSize systematically "visit" each node in a tree
 - This is called a *traversal*
 - We also used this word in connection with lists
- Traversal is a common pattern in many algorithms
 - The processing done during the "visit" varies with the algorithm
- What order should nodes be visited in?
 - Many are possible
 - Three have been singled out as particularly useful for binary trees: *preorder*, *postorder*, and *inorder*

2/20/2012

(c) 2001-4, University of Washington

22-11

Traversals

- **Preorder** traversal:
 - "Visit" the (current) node first
i.e., do what ever processing is to be done
 - Then, (recursively) do preorder traversal on its children, left to right
- **Postorder** traversal:
 - First, (recursively) do postorder traversals of children, left to right
 - Visit the node itself last
- **Inorder** traversal:
 - (Recursively) do inorder traversal of left child
 - Then visit the (current) node
 - Then (recursively) do inorder traversal of right child

Footnote: pre- and postorder make sense for all trees; inorder only for binary trees

2/20/2012

(c) 2001-4, University of Washington

22-12

Example of Tree Traversal

In what order are the nodes visited, if we start the process at the root?

Preorder:

Inorder:

Postorder:

2/20/2012

(c) 2001-4, University of Washington

22-13

More Practice

What about this tree?

Preorder:

Inorder:

Postorder:

Runtime analysis?

(c) 2001-4, University of Washington

22-14

New Algorithm: *contains*

Return whether or not a value is an item in the tree

// within class BinTree

```

/** Return whether elem is in tree */
public boolean contains(Object elem) {
    return subtreeContains(root, elem);
}

// Return whether elem is in (sub-)tree with root r
private boolean subtreeContains(BTNode<E> r, Object elem) {
    if (r == null)
        return _____;
    else if (r.item.equals(elem))
        return _____;
    else
        return _____;
}
  
```

Let's trace this on a tree..

2/20/2012

(c) 2001-4, University of Washington

22-15

Cost of *contains*

• Work done at each node:

• Number of nodes visited:

• Total cost:

• Can we do better?
